## PROBLEM SET 1

Show **ALL WORK** to get full/partial credit. Begin each problem on a new page, and clearly label each part of the problem.

- 1) (10 pts) A state variable X is related to the temperature by one of the two relations given below. At the freezing point of water (T=0 °C), measurements yield the value X=X<sub>I</sub>, and at the boiling point of water (T=100 °C) the value X=X<sub>S</sub>. For each case, determine the constant values a and b in terms of the two X values X<sub>I</sub> and X<sub>S</sub> and then derive an expression for the temperature in terms of X, X<sub>I</sub>, and X<sub>S</sub>.
  - a) X=aT+bb)  $X = e^{(T-b)/a}$
- 2) **(5 pts) Text, Problem 1.14**
- 3) (10 pts) A tank with volume V=0.5 m<sup>3</sup> contains oxygen ( $O_2$ ) at pressure P=1.5 x 10<sup>6</sup> Pa and temperature T=20 °C. Assume that oxygen can be treated as an ideal gas.
  - a) Determine the number of moles of oxygen in the tank.
  - b) Determine the mass of the oxygen in the tank.
  - c) Calculate the pressure that results if the temperature is increased to T=500 °C without changing the volume of the tank.
  - d) If the temperature is kept fixed at T=20 °C, how many moles of oxygen would have to be removed from the tank to make the pressure decrease to 10% of its original value?

4) (10 pts) Text Problem 1.16 – in part (a), a picture of the slab of air has been provided to help set-up the problem; the slab at rest implies that all forces must balance out; also it is suggested to express the mass of air in terms of the air density  $(\rho)$  time the slab of volume below.

in part (d), choose the temperature to be 20 °C at all four locations (might not be realistic for the top of Mt. Everest), and note that the molar mass of air is computed in problem 2).

- 5) **(5 pts) Text Problem 1.19** *hint:* calculate the two rms velocities separately at T=20 °C and then show that the ratio of the velocities does not depend on the temperature.
- 6) **(10 pts) Text Problem 1.31**
- 7) **(20 pts) Text Problem 1.34**

- 8) (20 pts) 200 moles of a monatomic ideal gas have an initial pressure P<sub>A</sub>= 2x10<sup>5</sup> Pa and occupy an initial volume V<sub>A</sub>=4.0 m<sup>3</sup>. In step 1 of a thermodynamic cycle, the gas pressure is increased isochorically to double its initial value. In step 2 the gas is allowed to expand isothermally until the pressure has returned to its initial value, and in step 3, the gas is compressed isobarically until its volume has returned to its initial value. Note: at the end of the complete thermodynamic cycle, both the pressure and volume of the gas have returned to their initial values.
  - a) Make a PV diagram that shows all three steps of the complete thermodynamic cycle.
  - b) Calculate  $T_A$ , the initial temperature,  $T_B$ , the temperature at the end of the first step, and  $T_C$ , the temperature at the end of the second step.
  - c) Find V<sub>C</sub>, the volume at the end of the second step.
  - d) Determine the work done on the gas during each step and the total work done over the whole cycle.
  - e) Find the heat transferred to the gas during each step and the total heat transfer over the whole cycle.
  - f) Using the results of parts d) and e), show that the first law of thermodynamics is satisfied for this thermodynamic cycle.
